Abstract: In this paper, we report our investigation on material structure analysis of \( (Ba_{0.7}Sr_{0.3}Fe_{12}O_{19})_1-x-(Ba_{0.7}Sr_{0.3}TiO_3)x \) with \( x = 0.2, x = 0.5 \) and \( x = 0.8 \) composite system prepared by a mechanical alloying process to promote ferroic properties. It is shown that the \( x \)-ray diffraction patterns of each composition for the composite materials are the same. It was consisted of the mixture for the two phases. The average of particle size for each respective phase in the composite materials was found initially increased up to 18-20 \( \mu m \) after mechanically milled for 40 hours, then start to decreased to a smaller size \( \approx 8-10 \mu m \) after 80 hrs milling time. However, a plot of particle size against the milling time for each composite phase showed a trend of further reduction in the mean particle sizes. In addition, the \( x \)-ray traces of dense pellet samples after sintering the milled powders at a temperature of 1100 °C showed broadened diffraacted peaks pattern due to fine crystallites in the samples. Results of mean crystallite size determination of respective phases in the composite samples showed the same trend, a decrease with milling time toward values about 10 nm at 80 hrs milling time. Hence, sintering to the milled particles has promoted the formation of nanocrystal containing particles. When compared between the mean particle size and mean crystallite size of respective phase in the composite sample at 80 hrs milling time, it is found that the mean crystallite size for magnetic phase \( (B7S3F) \) was more than 100 times smaller than the mean particle size of composite particles. However, finer mean crystallite sizes were found in the ferroelectric phase \( (B7S3T) \) in which the mean was about 200 times smaller than the mean particle size.

Keywords: Mechanical alloying; ferroic; composite; permanent magnets

1. Introduction

Barium-strontium hexaferrite and barium-strontium titanate are both well established materials which widely used respectively for permanent magnets and piezoelectric applications. As the properties are a structure sensitive, materials structure must be properly designed to meet a specific application. Both types of materials have excellent chemical stability and relatively cheap to produce. Barium Strontium Titanate \( (Ba_0.7Sr_0.3TiO_3) \) is known as ferroelectric material and considered as a good candidate for high performance piezoelectric applications [1], [2]. Ferrite magnets such as Barium Strontium Hexaferrite \( (B-S-F) \) is widely used to a diversity applications such as magnetic, microwave and recording device [3]-[5]. However, in new type of materials the so-called multiferroic [6] the magnetization can be induced by electric fields and electric polarization by magnetic fields. Thus, it is not surprise to find that researchs on coupling between magnetic and electric fields effects such as mageneto electric (ME) in a material system have attracted great attentions of many researcher over the last few years [7]. The coupling effects between magnetization and electric polarization were shown also occurred in a multi-layer of two phase multiferroic material [8]. The effects raised due to intimate contact between the layer of magnetic phase and that of feroelectric phase which further facilitating the cyrtallite exchange interaction in interfacial areas of the multi-layer system.

In this paper, we report some results of our recent investigation on the study of crystallites exchange interacting effects in a two-phase bulk system. The system is a composite between magnetic phase of \( Ba_{0.7}Sr_{0.3}Fe_{12}O_{19}(B7S3F) \) and feroelectric phase of \( Ba_{0.7}Sr_{0.3}TiO_3(B7S3T) \) prepared by conventional mechanical milling technique. We present results of investigation on synthesis and material structure analysis of \( (Ba_{0.7}Sr_{0.3}Fe_{12}O_{19})_1-x-(Ba_{0.7}Sr_{0.3}TiO_3)x \) with \( x = 0.2, x = 0.5 \) and \( x = 0.8 \) composite system prepared by a mechanical alloying process. The magnetic properties of the composites are also discussed in this report.

2. Experiment

The materials respectively \( Ba_{0.7}Sr_{0.3}TiO_3 \) (coded \( B7S3T \)) and \( Ba_{0.7}Sr_{0.3}Fe_{12}O_{19} \) (coded \( B7S3F \)) were prepared through mechanical alloying route employing a planetary ball mill with ball to powder ratio 10:1 for 80 hrs. Stoichiometric quantities of the analytical-graded precursors \( BaCO_3, SrCO_3, Fe_2O_3 \) and \( TiO_2 \) with purity better than 99 % were mixed in a planetary ball mill. Milled powders of various milling time for respective composition were taken and successively sintered at temperature 1100 °C to produce fully crystalline materials. The sintered powders were analysed by Particle Size Analyser for the average particle size determination.

Additional analysis by XRD was performed on an overlapping diffraction peak employing step scanning and calculation for crystallite size determination using Debye Scherer formula[9] :

\[
d = 0.9 \times \lambda / \beta \times \cos \theta
\]

Where \( d \) is the mean crystallite size, \( \lambda \) is the X-ray wavelength, \( \beta \) is the full width at half maximum (FWHM) of a diffraction peak after correcting for instrumental peak broadening (\( \beta \) expressed in radians), \( \theta \) is the Bragg angle. Peak broadening due to lattice strain was neglected.
Preparation steps for \((\text{Ba}_{0.7}\text{Sr}_{0.3}\text{Fe}_{12}\text{O}_{19})_{1-x} (\text{Ba}_{0.7}\text{Sr}_{0.3}\text{TiO}_3)_x\) with \(x = 0.2\), \(x = 0.5\) and \(x = 0.8\) composite system were carried out by a mixing the respective component materials with the right mass fraction and successively co-milled in the planetary ball milling apparatus leading to a homogeneous mixture in the composite network. The milled mixture was then pressed into a cylindrical die of 25 mm diameter to form a green pellet. The pellet was sintered at 1050 °C for 5 hours towards dense composites. Powders morphology was observed under Scanning Electron Microscope. The magnetic properties of composite samples were evaluated by a permagraph equipped with an external magnetic field up to 2.3 T.

3. Result and Discussion

Plots of diffraction traces for \(\text{Ba}_{0.7}\text{Sr}_{0.3}\text{Fe}_{12}\text{O}_{19})_{1-x} (\text{Ba}_{0.7}\text{Sr}_{0.3}\text{TiO}_3)_x\) composite samples with \(x = 0.2\), \(x = 0.5\) and \(x = 0.8\) is shown in Figure 1. All diffraction peaks for each x-ray diffraction trace were carefully identified and found that the trace consisted of a mixture between diffraction trace of \(\text{BaTiO}_3\) and that of \(\text{BaO}_6(\text{Fe}_2\text{O}_3)\). No other phases were found in the diffraction trace. Thus, a sintering treatment at 1050 °C for 5 hours to the composite samples has resulted in a two-phase mixture material which consisted of \((\text{Ba},\text{Sr})\text{TiO}_3\) and \((\text{Ba},\text{Sr})\text{O}_6(\text{Fe}_2\text{O}_3)\). The intensity of all diffracted peaks for \(\text{Ba}_{0.7}\text{Sr}_{0.3}\text{TiO}_3\) increased proportionally as the fraction \(x\) increased. This is in contrary with those of \(\text{Ba}_{0.7}\text{Sr}_{0.3}\text{Fe}_{12}\text{O}_{19}\) and thus confirm the composition of composite samples qualitatively. We have carried out quantitative analysis to the diffraction traces from which results of analysis is presented in Table 1. Composite samples with \(x = 0.2\), 0.5 and 0.8 must have mass fraction ratio \(\text{Ba}_{0.7}\text{Sr}_{0.3}\text{Fe}_{12}\text{O}_{19}/\text{Ba}_{0.7}\text{Sr}_{0.3}\text{TiO}_3\) respectively 4.0, 1.0 and 0.25. Thus, results of quantitative analysis for the mass fraction of phases as listed in Table 1 for the three samples have confirmed the designated value for the mass fraction of phases present in the composite samples.

When the mean particle size and mean crystallite size of respective phase in the composite samples are compared, it was found that the mean crystallite size for magnetic phase (B₇S₃F) was more than 100 times smaller than the mean particle size of composite particles. However, finer mean crystallite sizes were found in the ferroelectric phase (B₇S₃T) in which the mean was about 200 times smaller than the mean particle size.

Fig 4 and Fig 5 shows the morphology of based materials and composite B₇S₃F-B₇S₃Tcrystallite observed by the scanning electron microscope. Moreover, of a fracture of the tested composite in presented in the figure 7 for each combined composite material for composition x = 0.2, x = 0.5, x = 0.8

Figure 4. SEM Result for materials (a) B₇S₃T, and (b). B₇S₃F

During observed of morphology of crystallite and fractures of composite’s samples it was observed that the distribution of crystal in matrix in irregular. Crystallite has irregular shape and size.

Figure 5. Morphology of composite (a). B₇S₃F-B₇S₃T, x = 0.2, (b). B₇S₃F-B₇S₃T, x = 0.5, (c). B₇S₃F-B₇S₃T, x = 0.8

4. Conclusion

On the light of the discussion as described above, some conclusions can be drawn. The (Ba₀.₇Sr₀.₃Fe₁₂O₁₉)₁-ₓ(Ba₀.₇Sr₀.₃TiO₃)ₓ with x = 0.2, x = 0.5 and x = 0.8 composites were successfully prepared by mechanically milling the crystalline materials of the composite components. All composites consisted of the mixture of two phases. The mean crystallite size for magnetic phase (B₇S₃F) in the composite was more than 100 times smaller than the mean particle size of composite particles. However, finer mean crystallite sizes were found in the ferroelectric phase (B₇S₃T) in which the mean was about 200 times smaller than the mean particle size. This research will be continued to multiferroic materials.
