Abstract: A comparative study is made between the PI controller and fuzzy controller demonstrating the speed control of dual induction motor using fuzzy logic controller under unbalanced conditions. The dual induction motor is controlled by weighed vector value and the process of finding the weighed vector value is presented. The simulation is done in the MATLAB platform to study the effectiveness of the control.

Keywords: Dual Induction Motor, Fuzzy logic controller, PI (Proportional Integral) Controller, Summation torque, Unbalanced condition, Weighed Vector control and Weighed vector value.

1. Introduction

Implementation of coordination control of multiple induction motor is very important in industrial applications and transportation systems. There are two categories in coordination control of multiple induction motor. They are 1) Single inverter driving multiple induction motors. 2) Multiple inverter driving multiple induction motors.

The later control is complex because of the increase in number of IGBTs. The single inverter driving multiple induction motor find more advantages because of low cost, light weight, compact structure and less IGBTs. The single inverter drive system can be further divided as follows 1) Multiple-leg inverter control. 2) Vector control.

Multiple leg inverter control found to have its own disadvantages because of increased use of IGBTs. In vector control of multiple induction motor, some strategies were proposed to control multiple motor fed by the single inverter.

1.1 Objectives

The objective of the thesis are listed below
1) To improve the control of dual induction motor fed by a single inverter during unbalanced load condition using fuzzy logic controller.
2) To determine the weighed vector value necessary for controlling the dual induction motor.
3) To simulate the speed control of dual induction motor in MATLAB platform.

2. PI Controller

The system involves in the speed control of dual fed induction motor fed by single inverter using weighed vector control. The control process is survived by the PI controller unit which controls the stator current and the rotor flux produced in the motors. The weighed value is calculated under unbalanced load conditions, which possess the further operation of the motors without disturbance. Thus allowing the independent operation of the two induction motors.

2.1 Fuzzy controller

The system involves in the speed control of single inverter dual fed induction motor using fuzzy logic controller. The weighed values are calculated by the fuzzy controllers using the summation torque and stator current of the motors so that the weighed value controls the speed of the induction motor under unbalanced load conditions. The independent operation of the motors depends on the controlled current input from the controller, thus under unbalanced load conditions the weighed value is calculated and the feedback is given to the controller for better operation.
3. Modeling of Induction Motor

3.1 Mathematical descriptions of ac induction motors

There are a number of AC induction motor models. The model used for vector control design can be obtained by using the space vector theory. The 3-phase motor quantities (such as voltages, currents, magnetic flux, etc.) are expressed in terms of complex space vectors [7]. Such a model is valid for any instantaneous variation of voltage and current and adequately describes the performance of the machine under both steady-state and transient operation. Complex space vectors can be described using only two orthogonal axes. The motor can be considered a 2-phase machine. The utilization of the 2-phase motor model reduces the number of equations and simplifies the control design.

3.2 Space vector definition [4]

Assume that $I_{sa}$, $I_{sb}$, and $I_{sc}$ are the instantaneous balanced 3-phase stator currents:

$$I_{sa} + I_{sb} + I_{sc} = 0 \quad (3.1)$$

The stator current space vector can then be defined as follows:

$$I_s = k (I_{sa} + a I_{sb} + a^2 I_{sc}) \quad (3.2)$$

Where, $a$ and $a^2$ = The spatial operators ($a = e^{j2\pi/3}$, $a^2 = e^{j4\pi/3}$)

$k = $ the transformation constant ($k=2/3$)

The space vector defined by equation (3.2) can be expressed utilizing the two-axis theory, the stator current space vector in the stationary reference frame attached to the stator can be expressed as:

$$I_s = I_{sa} + j I_{sb} \quad (3.3)$$

The equation (3.4) shows the actual 3-phase stator currents as

$$I_{a} = k(I_{sa} - \frac{1}{2} I_{sb} - \frac{1}{2} I_{sc}) \quad (3.4)$$

$$I_{b} = k\frac{a}{2} (I_{sb} - I_{sc}) \quad (3.5)$$

where, $k=2/3$ is a transformation constant

The space vectors of other motor quantities (voltages, currents, magnetic fluxes, etc.) can be defined in the similar way as the stator current space vector.

3.3 AC Induction motor model

The AC induction motor model is given by the space vector form of the voltage equations. The system model defined in the stationary $\alpha$, $\beta$-coordinate system attached to the stator is expressed by the following equations. Considering the initial condition of the motor model is symmetrical, with a linear magnetic circuit characteristic.

1) The stator voltage differential equations

$$u_{sa} = R_s I_{sa} + \frac{d}{dt} \psi_{s\alpha} \quad (3.6)$$

$$u_{sb} = R_s I_{sb} + \frac{d}{dt} \psi_{s\beta} \quad (3.7)$$

2) The rotor voltage differential equations

$$u_{r\alpha} = R_r I_{r\alpha} + \frac{d}{dt} \psi_{r\alpha} + \omega \psi_{s\beta} = 0 \quad (3.8)$$

$$u_{r\beta} = R_r I_{r\beta} + \frac{d}{dt} \psi_{r\beta} + \omega \psi_{s\alpha} = 0 \quad (3.9)$$

3) The stator and rotor flux linkages expressed in terms of the stator and rotor current space vector

$$\psi_{s\alpha} = L_{sa} I_{sa} + L_{sb} I_{sb} \quad (3.10)$$

$$\psi_{s\beta} = L_{sa} I_{sa} + L_{sb} I_{sb} \quad (3.11)$$

$$\psi_{r\alpha} = L_{ra} I_{r\alpha} + L_{rb} I_{r\beta} \quad (3.12)$$

$$\psi_{r\beta} = L_{ra} I_{r\alpha} + L_{rb} I_{r\beta} \quad (3.13)$$

4) Electromagnetic torque expressed by utilizing space vector quantities

$$T_e = \frac{3}{2} \frac{d}{dt} (\psi_{s\alpha} I_{r\beta} - \psi_{s\beta} I_{r\alpha}) \quad (3.14)$$

4. Controllers

4.1 PI controller

Proportional & Integral Controllers (PI) controllers were developed because of the desirable property that systems with open loop transfer functions of type 1 or above have zero steady state error with respect to a step input [6].

Proportional action: responds quickly to changes in error deviation.

Integral action: is slower but removes offsets between the plant’s output and the reference.
4.1.1 Formulation of PI feedback

<table>
<thead>
<tr>
<th>Table 4.1: Symbols used</th>
</tr>
</thead>
<tbody>
<tr>
<td>Symbols</td>
</tr>
<tr>
<td>$u$</td>
</tr>
<tr>
<td>$k_p$</td>
</tr>
<tr>
<td>$k_i$</td>
</tr>
<tr>
<td>$e$</td>
</tr>
<tr>
<td>$\tau$</td>
</tr>
<tr>
<td>$\tau_r$</td>
</tr>
<tr>
<td>$i_d$</td>
</tr>
<tr>
<td>$i_q$</td>
</tr>
</tbody>
</table>

The definition of proportional feedback control is

$$u = k_p e$$  \hspace{1cm} (4.1)

The definition of the integral feedback control is

$$u = k_i \int e dt$$  \hspace{1cm} (4.2)

In the PI controller we have a combination of P and I control, i.e. involving equations (4.1) and (4.2)

$$u = k_p e + k_i \int e dt$$  \hspace{1cm} (4.3)

$$u = k_p e + \frac{1}{\tau_i} \int e dt$$  \hspace{1cm} (4.4)

$$u = k_p (e + \frac{1}{\tau_i} \int e dt)$$  \hspace{1cm} (4.5)

Thus the equation (4.5) gives the combined feedback of P and I controller.

4.1.2 Tuning PI controllers

The general approaches to tuning of PI controllers are listed below.
1) Initially have no integral gain (TI large, I controller is in off condition)
2) Increase KP until get satisfactory response
3) Start to add in integral (decreasing TI) until the steady state error is removed in satisfactory time (may need to reduce KP if the combination becomes oscillatory).

4.1.3 Role of PI controller in the project

The PI controller controls the flow of stator current and regulates the $i_d$ and $i_q$ currents with $k_p$ and $k_i$ values.

4.2 Fuzzy controllers

Fuzzy controllers are very simple conceptually. They consist of an input stage, a processing stage, and an output stage. The input stage maps sensor or other inputs, such as switches, thumbwheels, and so on, to the appropriate membership functions and truth values. The processing stage invokes each appropriate rule and generates a result for each, then combines the results of the rules. Finally, the output stage converts the combined result back into a specific control output value.

4.2.1 Fuzzy rules

Fuzzy rules are used in fuzzy control in order to define the map from the fuzzy input signals (error signals, measured signals, or command signals) of the fuzzy controller to its fuzzy output signals (control signals)[1].

4.2.2 Role of fuzzy controller in the project

The Fuzzy controller controls the flow of stator current and regulates the i d-axis and i q axis currents with the fuzzy rules.

5. Weighed Vector Control

5.1 Weighed Vector Control of Induction Motor [2]

The dual induction motors fed by the single inverter has same frequency voltage. The various slip between the two induction motors is caused due to unbalanced load, which results in different speed and stator current of the two induction motors. Generally, the equal vector management is applied to calculate the given excitation current and force current within the existing method [4]. The weighted value $k_{\text{im}}$ is defined to process the vector control strategy. The figure 2 illustrates the rotor flux and the stator current in d–q axis.

</tbody>
</table>
The rotor flux linkage, stator current, and angular velocity necessary for finding the weighed vector are shown in the equations (5.1), (5.2) and (5.3).

\[
\frac{d\psi_r}{dt} + (S_r + j(w_s - w_r))\psi_r = L_m S_r i_{q1}^r \\
\frac{d\psi_i}{dt} + (S_r + j(w_s - w_r))\psi_i = L_m S_r i_{q2}^i \\
\frac{d(2\psi_f^e + k_w \Delta \psi^e)}{dt} = S_i L_m (2\psi_f^e + k_w \Delta \psi^e) - S_i (2\psi_f^e + k_w \Delta \psi^e) + j(k_w \Delta w_r \psi_f^e + k_w \Delta w_r \Delta \psi_f^e) \\
\quad - (w_s - w_r)(2\psi_f^e + k_w \Delta \psi^e) \\
\frac{dl_1}{dt} = S_i L_m \Delta \psi^e - S_r \Delta \psi^e + j(w_s - w_r - k_w \Delta w_r)\Delta \psi^e + jw_r \psi_f^e \\
k_w = 2k_m - 2k_m + 1 \\
k_a = 2k_m - 1
\]

5.2 Calculation of stator current

The equation (5.4) represents the flux linkage and stator current in d and q axis. The rotor flux oriented state equations of the induction motors are given in equation (5.5)

On Substituting equations (5.1), (5.2) and (5.3) in equation (5.6) we obtain equation (5.7)

\[
\frac{k_w d\psi_d^e}{dt} = L_m S_r (2\psi_d^e + k_w \Delta \psi_d^e) - S_r (2\psi_d^e + k_w \Delta \psi_d^e) + ((w_s - w_r)k_w - k_m \Delta w_r)\Delta \psi_d^e \\
\frac{k_w d\psi_q^e}{dt} = (k_w \Delta w_r - 2(w_s - w_r))\psi_q^e - S_r k_w \Delta \psi_q^e + (k_m \Delta w_r - k_w (w_s - w_r))\Delta \psi_q^e + L_m S_r (2\psi_q^e + k_w \Delta \psi_q^e) \\
\frac{d\psi_d^e}{dt} = L_m S_r \Delta \psi_d^e - S_r \Delta \psi_d^e + (w_s - w_r - k_w \Delta w_r) \Delta \psi_d^e \\
\frac{d\psi_q^e}{dt} = L_m S_r \Delta \psi_q^e - S_r \Delta \psi_q^e + \Delta w_r \psi_q^e - k_w (w_s - w_r - k_w \Delta w_r) \Delta \psi_d^e.
\]

5.3 Calculation of summation torque

In order to find the weigh torque value, the torque of each motor must be determined and summed, they are represented as \(T_1\) and \(T_2\). The summation torque of the dual induction motor is given by \(T_s\)

\[
T_s = T_1 + T_2 \\
T_1 = \psi_f^e \times i_{q1}^r \\
T_2 = \psi_f^e \times i_{q2}^i \\
T_s = T_1 + T_2 = k_x (\psi_f^e \times i_{q1}^r + \psi_f^e \times i_{q2}^i) \quad \text{(5.10)}
\]

Where,

\[
k_x = 1.5 \pi_p \frac{L_m}{L_r}
\]

Now expanding equation (2.10) by Substituting equation (5.1) and (5.2), The summation torque is given in equation (5.12)
The summing torque in the d-q frame is obtained by substituting equation (5.4) in the equation (5.12)

5.4 Calculation of reference current

The reference stator current expression in q-axis is obtained as follows

\[ i_{qs}^* = \frac{1}{2\psi_{dr}^*} \left( i_{qs} - k_n (\Delta \psi_{q}^* - \Delta \psi_{q}^{p}) - k_n (\Delta \psi_{dr}^* - \Delta \psi_{dr}^{p}) \right) \]

5.5 Weighed Value Calculations

5.5.1 Methods for weighed value calculation

The characteristics of dual induction motors fed by single inverter can be defined in two ways on the basis of the load applied to the machine.

1) Speed relevant system
2) Speed irrelevant system

5.5.1.1 Speed relevant system

In this system the speed of each motor is independent and determined by its own torque. The proportional relation of the components of these two motors will be similar thus it is enough to control the torque difference of the motors.

5.5.1.2 Speed irrelevant system

In this system the speed of each motor varies according to the unbalanced load applied to the motor. The slip with the speed of the motors is influenced by the differential torque of the motors.

5.5.2 Calculation of the Weight value

The weight value \( k_m \) consists of two components say

1) Torque component \( k_{mt} \)
2) Speed component \( k_{ms} \)

The components are calculated by the practical torque and speed obtained which are illustrated as

\[ k_{mt} = \frac{t_1}{t_1 + t_2} \]

\[ k_{ms} = k_{ms} + \text{sign}(k_{msd})d_p \quad k_{msd} \geq d_x \]

\[ k_{ms} = k_{ms} - \text{sign}(k_{msd})d_{n} \quad k_{msd} < d_n \]

6. Results Using PI Controller

6.1 Simulation of speed control of dual IM using PI controller

The figure 6.1 depicts the simulation of vector speed control of dual induction motor implementing PI controller developed in the MATLAB.
7. Results Using Fuzzy Controller

7.1 Simulation of speed control of dual IM using fuzzy controller

The figure 7.1 depicts the simulation of vector speed control of dual induction motor implementing fuzzy controller developed in the MATLAB.

![Figure 7.1: Simulation of Speed control of Dual Induction motor using fuzzy Controller](image)

8. Inference

From the figure 6.2, 6.3 and figure 7.2, 7.3 it is clear that the starting torque is obtained well while using fuzzy controller and the harmonics is also considerably low.

9. Conclusion

In this project work, the weighed vector speed control of dual induction motor using fuzzy logic controller under unbalanced load condition is demonstrated. A frame work is developed for obtaining the weighed vector value. Modeling of induction motor is also presented.

A simulation is done in MATLAB to accomplish the weighed vector control of dual induction motor. The effectiveness of the system is analyzed through the graph achieved from the simulation. The result shows that the fuzzy logic controller is more effective than PI controller in controlling dual induction motor speed.

10. Future Scope

As a future work, the hardware of the project can be implemented and more advanced controller can be used instead of fuzzy controllers.
