Abstract: In this paper we study numerical methods for second order hybrid fuzzy fractional differential equations and the variational iteration method is used to solve the hybrid fuzzy fractional differential equations with a fuzzy initial condition. We consider a second differential equation of fractional order and we compared the results with their exact solutions in order to demonstrate the validity and applicability of the method. We further give the definition of the Degree of Sub element hood of hybrid fuzzy fractional differential equations with examples.

Keywords: hybrid fuzzy fractional differential equations, Degree of Sub Element Hood

1. Introduction

With the rapid development of linear and nonlinear science, many different methods such as the variational iteration method (VIM) [1] were proposed to solve fuzzy differential equations. Fuzzy initial value problems for fractional differential equations have been considered by some authors recently [2, 3]. To study some dynamical processes, it is necessary to take into account imprecision, randomness or uncertainty. The uncertainty can be modelled by incorporating it into the dynamical system and considering fuzzy differential equations. The origins of fractional calculus go back to 1695 when Leibniz considered the derivative of order 1/2. Miller and Ross [8] and Oldham and Spanier [9] provide historical details on the fractional calculus. Many applications have been found for fractional calculus, some of which are discussed in Debnath [5] and Podlubny [12]. In particular, fractional differential equations have received much attention and a number of recent works concern their numerical solution (see Ford and Connolly [6] and others).

As another development, hybrid systems are dynamical systems that progress continuously in time but have formatting changes called modes at a sequence of discrete times. Some recent papers about hybrid systems include [4, 7, 13]. When the continuous time dynamics of a hybrid system comes from fuzzy fractional differential equations the system is called a hybrid fuzzy fractional differential system or a hybrid fuzzy fractional differential equation. This is one of the first papers to study hybrid fractional differential equations. The aim of this paper is to study their numerical solution.

This paper is organized as follows. In Section 2, we provide some background on fuzzy fractional differential equations and hybrid fuzzy fractional differential equations. In Section 3 we discuss the numerical solution of hybrid fuzzy fractional differential equations by Runge Kutta 4th order method. The method given uses piecewise application of a numerical method for fuzzy fractional differential equations. In Section 4, as an example, we numerically solve the Degree of Sub element hood of hybrid fuzzy fractional differential equations. The objective of the present paper is to extend the application of the variational iteration method, to provide approximate solutions for fuzzy initial value problems of differential equations of fractional order, and to make comparison with that obtained by an exact fuzzy solution.

2. Hybrid Fuzzy Fractional Differential Equations

Preliminaries

In this section the most basic notations used in fuzzy calculus are introduced. We start with defining a fuzzy number.

We now recall some definitions needed through the paper. The basic definition of fuzzy numbers is given by Ford and Connolly [6] and others).

endpoint of \([u]\). Since each \(y \in R\) can be regarded as a fuzzy number \(Y\) defined by

\[
Y(i) = \begin{cases} 
1 & \text{if } t = y \\
0 & \text{if } t \neq y 
\end{cases}
\]

Definition 1

A fuzzy number (or an interval) \(u\) in parametric form is a pair \((u_L, u_U)\) of functions \(u(r), \bar{u}(r), 0 \leq r \leq 1\), which satisfy the following requirements:

1) \(u(r)\) is a bounded non-decreasing left continuous function in \((0, 1]\) and right continuous at 0.

2) \(\bar{u}(r)\) is a bounded non-decreasing left continuous function in \((0, 1]\) and right continuous at 0.

3) \(u(r) \leq \bar{u}(r), 0 \leq r \leq 1\).

Let us consider the following fractional differential equation:

\[
\frac{d^\beta}{dt^\beta} x(t) = f(t, x(t), \lambda^*(x(t))), \quad t \in [t_k, t_{k+1}] \quad (1)
\]

where, \(0 \leq t_0 \leq t_1 \leq \ldots \leq t_k \rightarrow \infty\)

\(f \in C[R^* \times E \times E, E], \lambda^*_k \in C[E,E]\)

Here we assume that the existence and uniqueness of solution of the hybrid system hold on each \([t_k, t_{k+1}]\) to be specific the system would look like:

\[
\frac{d^\beta}{dt^\beta} x(t) = \begin{cases} 
\frac{d^\beta}{dt^\beta} x_0(t) = f(t, x_0(t), \lambda_0(x_0(t))), x(t_0) = x_0, t \in [t_0, t_1] \\
\frac{d^\beta}{dt^\beta} x(t) = f(t, x(t), \lambda_1(x(t))), x(t_1) = x_1, t \in [t_1, t_2] \\
\vdots \\
\frac{d^\beta}{dt^\beta} x(t) = f(t, x(t), \lambda_k(x(t))), x(t_k) = x_k, t \in [t_k, t_{k+1}]
\end{cases}
\]

By the solution of (1) we mean the following function:

\[
x(t) = x(t, t_0, x_0) = \begin{cases} 
x_0(t), t \in [t_0, t_1] \\
x_1(t), t \in [t_1, t_2] \\
\vdots \\
x_k(t), t \in [t_k, t_{k+1}]
\end{cases}
\]

We note that the solutions of (1) are piecewise differentiable in each interval for \(t \in [t_k, t_{k+1}]\) for a fixed \(x_k \in E\) and \(k = 0, 1, 2, \ldots\)

We can also represent a fuzzy numbers \(x \in E\) by a pair of functions,

\[
\frac{d^\beta}{dt^\beta} x(t) = \frac{d^\beta}{dt^\beta} [x(t, r), \bar{x}(t, r)]
\]

Using a representation of fuzzy numbers we may represent \(x \in E\) by a pair of functions \((\acute{x}(r), \bar{x}(r))\), \(0 \leq r \leq 1\), such that:

- \(\acute{x}(r)\) is bounded, left continuous and non decreasing,
- \(\bar{x}(r)\) is bounded, left continuous and non increasing and
- \(\acute{x}(r) \leq \bar{x}(r), 0 \leq r \leq 1\)

Therefore, we may replace (1) by an equivalent system equation (2):

\[
\begin{cases} 
\frac{d^\beta}{dt^\beta} \xi(t) = f(t, x(t, \lambda(t)), x(t)), \xi(t_k) = x_k \\
\frac{d^\beta}{dt^\beta} \bar{\xi}(t) = \bar{f}(t, x(t, \lambda(t)), x(t)), \bar{\xi}(t_k) = \bar{x_k}
\end{cases}
\]

This possesses a unique solution \((\xi, \bar{\xi})\) which is a fuzzy function. That is for each \(t\), the pair \((\xi(t, r), \bar{\xi}(t, r))\) is a fuzzy number, where \((\xi(t, r), \bar{\xi}(t, r))\) are respectively the solutions of the parametric form given by Equation (3):

\[
\begin{cases} 
\frac{d^\beta}{dt^\beta} \xi(t) = F(t, x(t, r), \xi(t, r)), \xi(t_1; r) = x_1(r) \\
\frac{d^\beta}{dt^\beta} \bar{\xi}(t) = \bar{F}(t, x(t, r), \bar{\xi}(t, r)), \bar{\xi}(t_1; r) = \bar{x_1(r)}
\end{cases}
\]

for \(r \in [0, 1]\)

3. The Fourth Order Runge Kutta Method With Harmonic Mean For Second Order Differential Equations

For a second order hybrid fuzzy fractional differential equation we develop the fourth order Runge Kutta method with harmonic mean when \(f\) and \(\lambda^*_k\) in (1) can be obtained via the Zadeh extension principle from:

\(f \in [R^* \times R \times R, R]\) and \(\lambda^*_k \in C[R, R]\)

we assume that the existence and uniqueness of solutions of (1) hold for each \([t_k, t_{k+1}]\). For a fixed \(r\), to integrate the system in (3) \([t_0, t_1, [t_1, t_2], \ldots, [t_k, t_{k+1}], \ldots\) we replace each interval by a set of \(N_k\) discrete equally spaced grid points (including the end points) at which the exact solution \(x(t, r) = (\xi(t, r), \bar{\xi}(t, r))\) is approximated by some

\((\xi(t, r), \bar{\xi}(t, r)) \in [\xi(t, r), \bar{\xi}(t, r)]\).

For the chosen grid points on \([t_k, t_{k+1}]\) at \(t_n = t_k + nh_k, h_k = \frac{t_{k+1} - t_k}{N_k}\), \(0 \leq n \leq N_k\).

Let

\((\xi_k(t, r), \bar{\xi}_k(t, r)) \equiv (\xi_k(t, r), \bar{x}_k(t, r))\) and

\((\xi_k(t, r), \bar{\xi}_k(t, r)) \equiv (\xi_k(t, r), \bar{x}_k(t, r))\) may be denoted respectively by

\((\xi_k(t, r), \bar{\xi}_k(t, r)) \equiv (\xi_k(t, r), \bar{x}_k(t, r))\) and \((\xi_k(t, r), \bar{\xi}_k(t, r)) \equiv (\xi_k(t, r), \bar{x}_k(t, r))\).

We allow \(N_k\)’s to vary over the \([t_k, t_{k+1}]\)’s so that the \(h_k\)’s may be comparable.

The Fourth Order Runge Kutta method for (1) is given by:

\[\begin{align*}
Y_k(t, r) &= Y_{k-1}(t, r) + \lambda_k(t, r) \left( \frac{\lambda_k(t, r) - \lambda_{k-1}(t, r)}{2} \right) \\
\bar{Y}_k(t, r) &= \bar{Y}_{k-1}(t, r) + \lambda_k(t, r) \left( \frac{\lambda_k(t, r) - \lambda_{k-1}(t, r)}{2} \right)
\end{align*}\]

Where

\[\lambda_k(t, r) = \frac{Y_k(t, r) + \bar{Y}_k(t, r)}{2}\]
\[
\begin{align*}
\bar{k}_1(t_{k,n} ; y_{k,n} (r); z_{k,n} (r)) &= \min \left\{ h_k f (t_{k,n} , u, \lambda_k (u_k)) \right\} \\
&= \min \{ h_k f (t_{k,n} , u, \lambda_k (u_k)) \}, \\
&\quad \forall u \in \left\{ [y_{k,n} (r) , y_{k,n} (r)] , [\overline{z}_{k,n} (r) , \overline{z}_{k,n} (r)] \right\}, \\
&\quad \forall u_k \in \left\{ [y_{k,n} (r) , y_{k,n} (r)] , [\overline{z}_{k,n} (r) , \overline{z}_{k,n} (r)] \right\}, \\
\bar{l}_1(t_{k,n} ; y_{k,n} (r); z_{k,n} (r)) &= \max \left\{ h_k f (t_{k,n} , u, \lambda_k (u_k)) \right\} \\
&= \max \left\{ h_k f (t_{k,n} , u, \lambda_k (u_k)) \right\}, \\
&\quad \forall u \in \left\{ [y_{k,n} (r) , y_{k,n} (r)] , [\overline{z}_{k,n} (r) , \overline{z}_{k,n} (r)] \right\}, \\
&\quad \forall u_k \in \left\{ [y_{k,n} (r) , y_{k,n} (r)] , [\overline{z}_{k,n} (r) , \overline{z}_{k,n} (r)] \right\}, \\
\bar{k}_2(t_{k,n} ; y_{k,n} (r); z_{k,n} (r)) &= \min \left\{ h_k f (t_{k,n} + \frac{1}{2} (h_k) , u, \lambda_k (u_k)) \right\} \\
&= \min \left\{ h_k f (t_{k,n} + \frac{1}{2} (h_k) , u, \lambda_k (u_k)) \right\}, \\
&\quad \forall u \in \left\{ \Phi_{k_i} (t_{k,n} , y_{k,n}) \right\}, \\
&\quad \forall u_k \in \left\{ y_{k,0} (r) , y_{k,0} (r) \right\}, \\
\bar{l}_2(t_{k,n} ; y_{k,n} (r); z_{k,n} (r)) &= \max \left\{ h_k f (t_{k,n} + \frac{1}{2} (h_k) , u, \lambda_k (u_k)) \right\} \\
&= \max \left\{ h_k f (t_{k,n} + \frac{1}{2} (h_k) , u, \lambda_k (u_k)) \right\}, \\
&\quad \forall u \in \left\{ \Phi_{k_i} (t_{k,n} , y_{k,n}) \right\}, \\
&\quad \forall u_k \in \left\{ y_{k,0} (r) , y_{k,0} (r) \right\}, \\
\end{align*}
\]
\[
\begin{align*}
&k_1(t, n; y_k, z_k) = y_k(r) + \frac{1}{2} (k_1(t, n; y_k, z_k), y_k(r), z_k(r)), \\
&k_2(t, n; y_k, z_k) = y_k(r) + \frac{1}{2} (k_2(t, n; y_k, z_k), y_k(r), z_k(r)), \\
&k_3(t, n; y_k, z_k) = y_k(r) + \frac{1}{2} (k_3(t, n; y_k, z_k), y_k(r), z_k(r)), \\
&k_4(t, n; y_k, z_k) = y_k(r) + \frac{1}{2} (k_4(t, n; y_k, z_k), y_k(r), z_k(r)).
\end{align*}
\]

Where

\[
\Phi_k(t, n; y_k, z_k) = \Phi_k(t, n; y_k, z_k) + \frac{1}{2} (\Phi_k(t, n; y_k, z_k), y_k(r), z_k(r)).
\]

Next we define:

\[
\begin{align*}
&S_k[I_k(n, y_k(r), y_k(r), y_k(r), y_k(r)) = \\
&\frac{1}{6} [k_1(t, n; y_k, z_k) + 2[k_2(t, n; y_k, z_k) + k_3(t, n; y_k, z_k)] + k_4(t, n; y_k, z_k)].
\end{align*}
\]

The exact solution at \( t, n+1 \) is given by:

\[
\begin{align*}
F_{k, n+1}(r) &= Y_k(r) + S_k[I_k, y_k(r), y_k(r), y_k(r), y_k(r)], \\
G_{k, n+1}(r) &= Y_k(r) + T_k[I_k, y_k(r), y_k(r), y_k(r), y_k(r)].
\end{align*}
\]

Degree of Sub Element hood:

Let \( X \) be a Universal, \( U \) be a set of parameters and let \( (F_{k, n+1}) \) and \( (G_{k, n+1}) \) are two fuzzy elements of \( X \). Then the degree of sub element hood denoted by \( \Phi(F_{k, n+1}; G_{k, n+1}) \) is defined as,

\[
\Phi(F_{k, n+1}; G_{k, n+1}) = \frac{1}{|F_{k, n+1}|} \left[ \left| (F_{k, n+1}) \right| - \max \left[ 0, \left| (G_{k, n+1}) \right| - \left| (F_{k, n+1}) \right| \right] \right].
\]

4. Numerical Example

In this section, we present the examples for solving second order hybrid fuzzy fractional differential equations.

Consider the following second order hybrid fuzzy fractional differential equation:

\[
D^\beta_c x(t) = Z \& D^\beta_c X(t) = Zx^2-y^2 \quad \ldots (5)
\]
X(0) = X₀,
where β ∈ (0,1], t > 0, and
X₀ is any triangular fuzzy number.
This problem is a generalization of the following hybrid fuzzy fractional differential equation:
\[ \begin{align*}
\epsilon D_{\alpha}^{\beta} x(t) &= z(t) = \left[ \hat{z}(t; \tau), \tilde{z}(t; \tau) \right] \frac{d}{dt}\left[ \hat{y}(t; \tau), \tilde{y}(t; \tau) \right] \\
\epsilon D_{\alpha}^{\beta} z(t) &= \left[ x(t; \tau), \hat{x}(t; \tau) \right] \left[ \hat{z}(t; \tau), \tilde{z}(t; \tau) \right]^2 \left[ \hat{y}(t; \tau), \tilde{y}(t; \tau) \right]^2
\end{align*} \] …..(6)

\[ x(t) = x_0, \]
Where β ∈ (0,1], t > 0, α is the step size and x₀ is a real number.

We can find the solution of the second order hybrid fractional fuzzy differential equation, by the method of Runge kutta 4th order Method. We compared & generalized the second order hybrid fractional fuzzy differential equation solution with the exact solution in the following table; also we illustrated the figure for this generalization by using Matlab.

### 5. Conclusion

In this paper, we have studied the second order hybrid fuzzy fractional differential equation. Final results showed that the solution of the second order hybrid fuzzy fractional differential equations approaches the solution of hybrid fuzzy differential equations as the fractional order approaches the integer order. The results of the study reveal that the proposed method with fuzzy fractional derivatives is efficient, accurate, and convenient for solving the second order hybrid fuzzy fractional differential equations.
