Nasolacrimal Duct Obstruction in Adults

Anila Monka1, Sulejman Zhugli2

University Hospital Centre “Mother Theresa” Tirana, Albania

Abstract: Evaluation of the results of DCR’s external technique with the use of silicon tubes in clinical improvement of patients and the factors that affect in preventing relapses. The study was conducted at the Department of Ophthalmology at UHC “Mother Theresa” which is tertiary center. One hundred thirty seven patients participated in the study, whose mean age was 56.1 (±15) with a range from 34 to 81 years. 22 (16%) of the patients were males and 115 (84%) females p<0.05). Five (3.6%) of total patients experienced a relapse while the success rate 96.4%. The success rate is 3.6 times higher external dacriocystorhinostomy as compared to patients treated without this technique (OR=3.6, 95%CI 1.46- 8.62, p<0.01). External DCR with silicone intubation has a high success rate. Disorders of the lacrimal system can be diagnosed from the history, signs symptoms, clinical examination, lab studies, imaging studies and other tests

Keywords: dacriocystorhinostomy silicone tubes, nasolacrimal duct obstruction, adults

1. Introduction

Obstruction of the nasolacrimal duct: It might be congenital or acquired. The congenital one has been discussed in the congenital anomalies of the lacrimal system. Acquired nasolacrimal duct obstruction, can occur at any age and is divided into primary and secondary. The primary acquired nasolacrimal duct obstruction (PANDO) is caused by inflammation, or fibrosis without any precipitating cause (1). It is more common in middle-aged and elderly females. They demonstrated using CT scans, that women have significantly smaller dimensions in the lower nasolacrimal fossa and middle nasolacrimal duct. They noted that changes in the anteroposterior dimensions of the bony nasolacrimal canal coincide with osteoprotic changes throughout the body (2). These may explain the prevalence of the disease in the middle-aged and elderly females. Hormonal changes that bring about a generalized deepithelization in the body may be the same within the lacrimal duct. An already narrow lacrimal fossa in women predispose them to obstruction by the sloughed off debris. The secondary acquired lacrimal duct obstruction (SALDO) is caused by inflammation or fibrosis with precipitating cause such as infectious, inflammatory, neoplastic, traumatic, or mechanical factors. Infections with bacteria, viruses, fungi and parasites have been implicated as causes of SALDO. Bacteria such Actinomyces, propioniobacterium, Fusobacterium, Bacteroides, Mycobacterium, and Chlamydia species have been associated with lacrimal drainage obstruction. Other bacteria include Nocardia, Enterobacter, Treponema pallidus, and Staphylococcus aureus. Viral causes are seen with herpetic infection (e.g Herpes simplex, Herpes zoster, Chichenpox, epidemic keratoconjunctivitis) (3). Fungi may obstruct lacrimal passages by forming stone (dacryolith) or cast. Species associated with obstruction are Aspergillus, Candida, Pityosporum and Trichophyton. Parasitic obstruction is rare but is reported in patients infected with Ascariis lumbricoids, which enters the lacrimal system through the valve of Hassner (4). Inflammation may be endogenous or exogenous in origin. Wagener granulomatosis and sarcoidosis are 2 examples of conditions that lead to obstruction due to progressive inflammation within the mucosa of the nasolacrimal passages. Other endogenously arising inflammation associated with lacrimal obstruction are cicatrical pemphigoid, sinus histiocyteosis, Kawasaki disease and scleroderma (5,6). Exogenous causes of cicatrical lacrimal drainage obstruction are systemic chemotherapy, bone marrow transplantation and radiation. Trauma can lead to scarring and obstruction of the lacrimal passage which might be iatrogenic following aggressive lacrimal probing, orbital decompression surgery, paranasal, nasal and craniofacial procedures. A number of cases of dacryostenosis have been reported after cosmetic rhinoplasty (7,8). Non-iatrogenic traumatic causes are either blunt or sharp trauma which most commonly involves the canaliculus, lacrimal sac, and nasolacrimal duct (9) squamous cell carcinoma can cause obstruction for the distal aspect of the nasolacrimal duct (10,11).External DCR in which the lacrimal sac is approached from outside via a short skin incision, a little bit of bone between the tear sac and the nose is removed in order to reach inside the nose, the tear sac is opened and stitched to the lining of the nose (nasal mucosa), a soft silicone tubing is placed from the upper and lower puncti through the tear ducts into the nose temporarily to keep the passage open. These tubes are usually removed between six and eight weeks after the operation (12).

2. Materials and Methods

A total 137 patients who had DCR surgery between 2013 and 2014 were prospectively reviewed in University Hospital Centre “Mother Theresa” in Tirana, Albania which is a tertiary referral hospital. All patients had primary nasolacrimal duct obstruction and no previous surgery for nasolacrimal duct obstruction. A complete ophthalmologic examination was performed. The patency of lacrimal drainage system was evaluated with lacrimal syringing. All patients were examined by otorhinolaryngology department and when needed assessed with computed tomography. Informed consent was taken from all patients. Age, gender, laterality, and the lacrimal irrigation in the third month visit were recorded. Surgical success was accepted as the patency of the formed ostium with lacrimal syringing/irrigation. All cases were done by a single surgeon (AG). Exclusion criteria were canalicular stenosis, epiphora due to adnexal, corneal, conjunctival diseases, and age less than 20 years of age. Descriptive methods and independent t-test were used

for statistical analyses and a p value <0.05 was accepted as significant.

3. Results and Discussion

One hundred thirty seven patients participated in the study, whose mean age was 56.1 (±15) with a range from 34 to 81 years. 22 (16%) of the patients were males and 115 (84%) females p <0.05. The mean age of men was 57.1 (±9.0) years (range 29-81 years), while women is changing age 50.5 (±9.8) years (range 32-70 years) between them statistically significant (t=3.9 p<0.01). Sociodemographic characteristics of patients are shown in table 1. The ratio of patients ≥60 years with patients <60 years was 1:1.1. Most of the patients, 108 or 79% of them live in urban areas while 29 (21%) of them live in rural areas, with statistically significant difference between them (p<0.01). It is noted a predominance of patients in the age group 51-60 years old with 36 (26.6%) of cases. Seven or 5.3% of patients suffered from acute DC, 24 (17.5%) suffered from chronic DC, 96 (70.2%) of chronic purulent DC and 10 patients from phlegmonous sacs. External dacryocystorhinostomy with silicone tube was carried out in all patients. The success rate and percentage of relapse were evaluated. Five (3.6%) of total patients experienced a relapse while the rate success rate 96.4%. The success rate is 3.6 times higher external dacryocystorhinostomy as compared to patients treated without this technique (OR = 3.6, 95%CI 1.46-8.62, p<0.01). The present signs and symptoms of nasolacrimal duct obstruction include epiphora, conjunctivitis, and mucoid discharge. Dacryocystitis may develop when bacterial growth occurs in the stagnant fluid of the lacrimal sac. Whereas acute dacryocystitis is usually characterized by tender preseptal cellulites, chronic dacryocystitis typically manifests as painless purulent reflux from the lacrimal sac. A rare risk of untreated, chronic dacryocystitis secondary to an acquired nasolacrimal duct obstruction is orbital cellulites (13). Dacryocystorhinostomy (DCR) is a surgical method for the treatment of the lacrimal excretory system obstructor. Obstruction of the passage of tears from the puncti through canalliculi, lacrimal sac and finally the nasolacrimal duct down to the nose can lead to stagnation of tear in the point before the obstruction, with continuous tearing and the resultant infection with continuous pus discharge into the eye, which may lead to ocular and peri-ocular infections with the possible sequelae of vision –or even – life threatening complications (14).When this infection is established in the lacrimal excretory parts, this leads usually to the destruction and fibrosis of the thin delicate canal which penetrates the tissue (including the bone) to excrete tears in the inferior part of the lateral wall of the nose, at this point there is no solution other than creating a new window through those tissues to permit tears to be excreted in the nose again (15).Since the introduction of external DCR subsequent modifications have ensured a high success rate and it remains the gold standard for treating of epiphora caused by nasolacrimal duct obstruction (16).

4. Conclusions

External DCR with silicone intubation has a high success rate. Disorders of the lacrimal system can be diagnosed from the history, signs symptoms, clinical examination, lab studies, imaging studies and other tests. The patient should be evaluated in a systemic manner and not all steps are needed because the diagnosis may be apparent with some simple tests.
